JOSS: ASSEMBLY LISTING OF THE SUPERVISOR

G. E. Bryan

This research is supported by the United States Air Force under Project RAND—Contract No. F44620-67-C-0045—monitored by the Directorate of Operational Requirements and Development Plans, Deputy Chief of Staff, Research and Development, Hq USAF. Views or conclusions contained in this Memorandum should not be interpreted as representing the official opinion or policy of the United States Air Force.

PREFACE

JOSS† is a multiuser, single-server computing system that provides for the solution of numerical problems. The system consists of a central computer containing the JOSS program and a number of typewriter consoles connected to the computer via telephone lines. The central computer turns its attention rapidly from console to console in such a way that individual users appear to have exclusive use of the system.

The JOSS supervisor is the unit that exercises overall control of the system's operation: Acting as a scheduling, resource-allocating, and synchronizing device, it ensures that all data and hardware necessary for a particular action are simultaneously available; it also meters the operation of the system to provide revenue accounting information and data describing system performance and user operations. This memorandum, an exact reproduction of the assembly listing of the JOSS supervisor, is a companion piece to RM-5216-PR, JOSS: User Scheduling and Resource Allocation[1] and RM-5217-PR, JOSS: Accounting and Performance Measurement,[2] which describe in detail the operation of the supervisor.

The division of the program listing into two parts represents two assemblies: Part I is the code for the core-resident JOSS supervisor, and Part II the code for system initialization and catastrophic error recovery routines. (The latter is required only at system start-up or when serious machine errors occur; during regular JOSS operation, it is overlaid by user information.) The code is written in MACRO-6, the machine assembly language for the Digital Equipment Corporation PDP-6, on which the JOSS system is implemented. (The PDP-6 instruction set and the assembly language are described in DEC's Handbook F-65[3] and Programming Manual: MACRO-6 Assembly Language.[4])

The Index to the Program Listing enumerates the routines and data storage of the program in order of occurrence, with headings and indentations suggesting the structure of the code. Because of the limited

---

†JOSS is the trademark and service mark of The RAND Corporation for its computer program and services using that program.

ability of MACRO-6 to provide for page titling and subtitling, the heading structure of the listing itself does not always correspond to the indentations of the Index. Page numbers given in the Index refer to the pagination of this memorandum and not to those printed out by the assembler in the heading line.

This work is part of The RAND Corporation's continuing research program in computer theory and applications, particularly the implementation of man-machine systems, under U.S. Air Force Project RAND. It should be useful to those with an interest in the field of time-shared interactive terminal systems.

SUMMARY

The code listed in this memorandum provides those functions in the JOSS system that are generally described by the terms monitor, supervisor, or executive. In particular, the routines perform the following tasks:

1. *Machine interrupt handling.* These programs provide appropriate responses to hardware interrupts from the drum system, the magnetic tape unit, the master console teletype, the real-time clock, programmed operators, and machine-detected hardware errors. (Interrupts from the user consoles and the disc file are handled by the console service and the disc service routines, respectively.)

2. *Supervision, resource allocation, and scheduling.* These routines provide overall supervision of the flow of work through the JOSS system; they allocate central processor time, core space, and input/output devices to the user, and schedule the use of these resources effectively to maintain high-speed response.

3. *Monitoring.* These are various routines that maintain accounting records for allocating usage charges, that meter the overall system activity, and that record the details of individual user behavior.

4. *User log-on and log-off.* These routines provide for initial user access to the system (by recording initials, project number, and department number) and produce final charge accounting records when the user leaves the system.

5. *System initialization.* In these routines, used only at system start-up, time of day and current date are requested and recorded, and a copy of the system is saved on the magnetic drum in case system recovery is required.

6. *Machine error recovery.* These routines provide for recovery from catastrophic machine failure by attempting to reload the system from the copy saved at initialization time. To aid in failure diagnosis, a message printed at the master console indicates the immediate symptom of the failure and records the contents of certain important registers.
